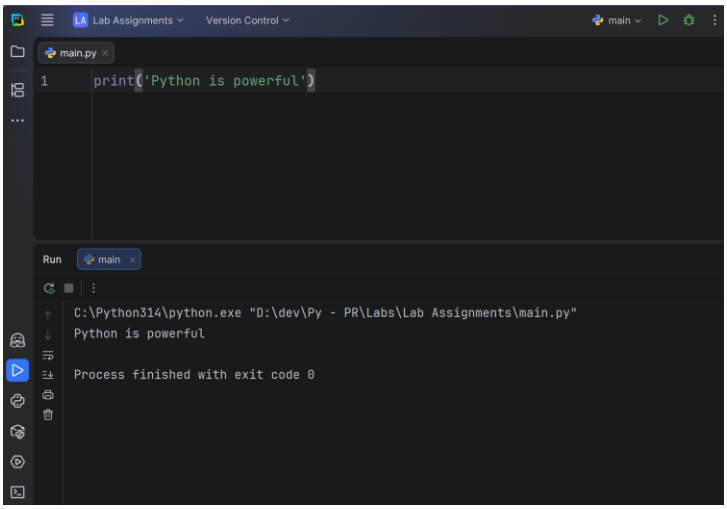
Week 01 - Lab Assignment

Create a simple Python command-line program that demonstrates the concepts learned this week.

Python: Basic Input and Output

To display information in Python, use the **print()** function. Here's a simple example:



The print() function displays the text that's inside the quotation marks.

print() Function Syntax

The sample above shows print() with just one argument. But the full print() function can accept several parameters:

Here's the full syntax:

`print(object, sep, end, file, flush)`

- object – The value(s) you want to print.
- sep (optional) – Lets you specify how multiple objects are separated in the output.
- end (optional) – Allows you to control what's printed at the end, such as a new line (`"\n"`) or tab (`"\t"`).
- file (optional) – Specifies where the output appears. The default is sys.stdout (your screen).
- flush (optional) – If True, the output is flushed right away. Default is False (buffered).

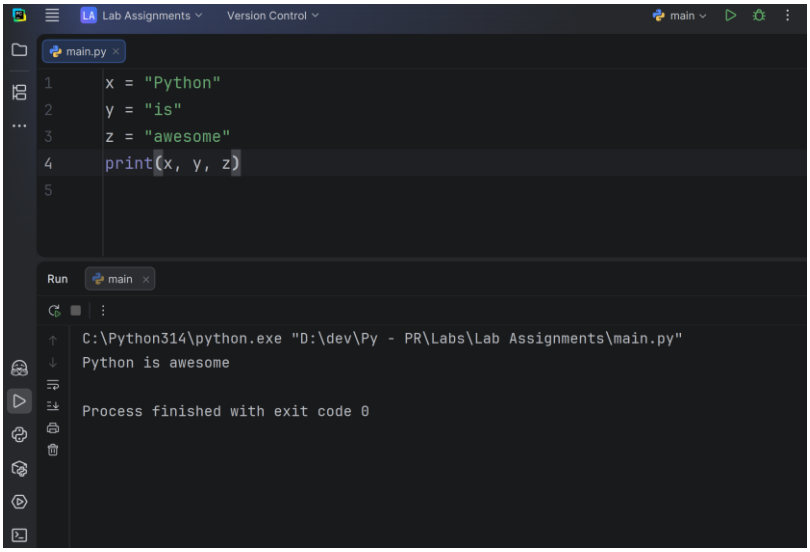
Example:



Installing Packages with Pip

Pip makes it easy to download and install Python packages. Packages available on pypi.org can be installed with this command:

pip install package-name

For example, to install the **emoji** package, run:

pip install emoji
